

The fight against cartels: a transatlantic perspective*

Emilie Dargaud[†], Andrea Mantovani[‡] and Carlo Reggiani[§]

July 2013

Abstract

The fight against cartels is a priority for antitrust authorities on both sides of the Atlantic. What differs between the EU and the US is not the basic toolkit for achieving deterrence, but to whom it is targeted. In the EU, pecuniary sanctions against the firm are the only instruments available to the Commission, while in the US criminal sanctions are also widely employed. The aim of this paper is to compare two different types of fines levied on managerial firms when they collude. We consider a profit based fine as opposed to a delegation based fine, with the latter targeting the manager in a more direct way. Under the assumption of revenue equivalence, we find that the delegation based fine, although distortive, is more effective in deterring cartels than the profit based one. When evaluating social welfare, a trade-off between deterrence and output distortion can arise. However, if the antitrust authority focuses on consumer surplus, then the delegation based fine is to be preferred.

Keywords: cartel policy, managerial firms, collusion.

1 Introduction

The past decade has witnessed an increase in price-fixing, market-sharing and bid-rigging cartel behaviour across the two sides of the Atlantic. As a consequence, the fight against cartels evolved from transnational to 'transatlantic', requiring unprecedented efforts and collaboration between US and EU antitrust authorities.¹ The most evident example is probably the gradual convergence of their corporate leniency programs, with the EU revisiting its legislation in 2002 on the basis of the US experience. Although some differences still remain, scholars and policy makers agree that the so-called "leniency revolution" (Spagnolo, 2008) brought forth a very effective tool for uncovering existing cartels on both sides of the Atlantic.

A similar convergence process did not occur in the sanctionatory procedure. The respective legal and enforcement regimes remain quite different in the US in comparison to the EU. Cartels are commonly treated as criminal offences in the US, where anticompetitive activities are sanctioned with fines of up to USD 1 million and/or with a sentence of up to ten years of imprisonment.² The situation is however different in the EU, where the violation of Art. 101 of the TFEU is generally not interpreted as a criminal offence. The imposition of pecuniary sanctions against cartel members is therefore the only instrument at the disposal of the Commission to use.³

In light of this, would it be in the best interest of the EU to also adopt criminal sanctions in order to crack down on cartel members? First, one should consider whether or not such criminalisation is feasible at the EU level. Recent interpretations under the current Treaty of Lisbon have stirred controversy, and the general opinion is that undertaking such a reform would require a long and costly process.⁴ Second,

¹The European Commission, the Department of Justice and the Federal Trade Commission cooperate together primarily on the basis of the 1991 Cooperation Agreement and of the 1998 "Positive Comity Agreement". The latter is also concerned with the exchange of information in cartel activities.

²The current level of sanctions are defined by the Antitrust Criminal Penalty Enhancement and Reform Act of 2004. In the ten year period 2003-2012, the US Courts sentenced 255 people to a total of 176,926 days of imprisonment. Statistics available on the US Department of Justice's website, <www.justice.gov/atr/public/workload-statistics.html>, accessed on 16 June 2013.

³The position held by the EU regarding the definition of criminal offences and sanctions is not completely clear. At the moment, national authorities in ten Member States can impose criminal sanctions, including imprisonment, against individuals involved in cartels (Massey, 2004, *e.g.*, explains the Irish case). Their use is, however, very limited.

⁴Reindl (2006), for example, argues that the Commission would have to increase its standard of proof in order to prove culpability. This could limit the number of cases that can be investigated.

many commentators reckon that such criminalisation, even if possible, would not be desirable in the socio-economic and cultural context of the EU.⁵

On these grounds, the purpose of this paper is not to provide a holistic comparison between two sanctionatory approaches influenced by two inherently different worldviews. Rather, we attempt to model, in a stylised way, the "punishing-the-firm versus punishing-the-person" controversy and better understand its economic effects. To this aim, we consider a model of repeated Cournot competition with managerial firms and study how the sustainability of collusion can be affected by different types of sanctions.

In particular, a representative antitrust authority has to decide between two types of penalties aimed at deterring cartel formation. The first type of penalty targets a firm's profit and it is the most commonly used instrument in the literature. The second type targets instead the manager's terms of contract and, in particular, its delegated powers. Although this stylised modelling device does not fully capture the idea of criminal sanction such as imprisonment, it does however constitute a first attempt to represent a measure intended to criminalise the collusive behaviour of managers. This represents the main novelty of the paper.

First, we demonstrate that both types of fines reduce the interval region where collusion can be sustained, although their effectiveness is dampened by delegation intensity. We then evaluate their relative performance. The main result is that, under a revenue equivalence assumption, a delegation based fine proves more effective in deterring collusion than a profit based fine.

We also consider welfare implications. The delegation based fine has a distortionary effect on the output level and may consequently have a negative effect on total surplus. This reveals the existence of a potential conflict between *ex ante* cartel deterrence and *ex post* output provision. In order to navigate such a trade-off, we compare the expected welfare generated by the two fines. The solution is straightforward if we limit our attention to consumer surplus, as we show that the delegation based fine is always preferred by consumers as well. However, when we consider total expected welfare, then the trade-off may reappear, as the choice between the two instruments depends on the combined effect of the delegation intensity and the amount of the fine.

⁵Khan (2012) provides a very interesting and thorough discussion on this issue. See also Buccirosi and Spagnolo (2007), who evaluate benefits and costs of imprisonment in terms of cartel deterrence.

Hence, under the basic assumptions and limitations of the model, our paper indicates that an antitrust authority mainly concerned with consumer protection should punish managers more directly. On the contrary, if the target is the interest of society at large, then *ex ante* and *ex post* efficiency can be restored only under certain specific conditions, and a delegation based fine is not always the best solution.

Related Literature

Since the pioneering work of Becker (1968), economists have developed an extensive literature related to "optimal sanctions".⁶ Sanctions should not only seek to punish detected cartels (ex-post efficiency) but also to discourage firms to engage in such illegal practices (ex-ante efficiency). We are mainly concerned with the deterrence effect of a sanction. Souam (2001) contributes to this line of research in that he considers the effect of revenue based fines as opposed to damage based fines. In his paper, however, what matters is how the fine is computed, not who should pay it.

A number of works have addressed the issue of imprisonment as a punishment for cartels and price fixers, the first and best known probably being Werden and Simon (1987). Gallo et al. (1994) present empirical evidence on the criminal punishment enforced in the USA and they compare it with the theoretical optimum. In a related paper, Craycraft et al. (1997) evaluate the fine levied in relation to the firm's ability to repay and take into consideration the value of the time spent in prison. Buccirosi and Spagnolo (2007) present simulation evidence to question the role of imprisonment in presence of leniency programs and whistleblowing. As underlined, our paper does not directly address imprisonment as a punishment for managers; however, we directly address the issue of punishing mainly the firm or the managers and to do so, we model a managerial firm.⁷

Cartels have received great deal of attention in the literature in recent years, mainly due to two factors. On the one hand, the activity of cartels is very common despite the efforts of antitrust authorities; on the other hand, the success of deterrence has been increased in the last decade mainly due to leniency programs. The seminal

⁶See, for example, Besanko and Spulber (1989), and more recent contributions as Buccirosi and Spagnolo (2007) and Allain et al. (2011), *inter alii*.

⁷In general, the use of criminal sanctions faced several opponents particularly in Europe where cartel practices do not produce strong moral disapproval. Wils (2002 and 2005) analyses the individual sanctions and imprisonment with particular reference to the EU situation.

paper by Motta and Polo (2003) has been followed by contributions that extend and discuss the use of leniency programs (Spagnolo, 2004; Aubert *et al.*, 2006; Chen and Rey, 2012). Aubert *et al.* (2006) focus on the different impact of reduced fines and positive rewards and find that rewarding individuals is more effective in deterring collusion. Although their paper is related to ours, the objective is very different: we do not focus on leniency and whistleblowing but on deterrence through fines, targeted either to the firms or to the managers.

The majority of the literature on cartels and collusion treats the firm as a profit-maximising decision maker, thereby deriving key insights on cartel stability and behaviour from a profit-maximising perspective. However, cartels often involve firms having separated ownership and control in such a way that the incentives of the key decision maker (CEO, manager) may not be fully aligned with those of the profit-maximising shareholders. A manager's objective depends on the structure of the incentives that the owner designs in order to motivate him. Owners often index managerial compensation to profit, sales and many other variables. The split between ownership and control can lead to non-profit-maximising behaviour particularly if managers are interested in maximising their own utility. For example, managers' reputation often relates to the size of the company and their decisions may be driven by "empire building" motivations rather than maximising the value of the firm for its shareholders (Baumol, 1958). The corporate governance factors can have a key impact on the operation of cartels.⁸

Our approach follows Vickers (1985) and Fershtman and Judd (1987): the owners of the firms can delegate some decisional power to their managers that have the objective of maximising a combination of profit and output, assumed to be a proxy of the size of the firm. Delegation affects the best responses of firms and impacts the strategic outcome of the game. This allows us to tackle the main research question in a relatively simple way. On top of that, the assumption of managerial firms reflects the observation that this is the nature of the majority of firms that raise the attention of antitrust authorities.⁹

⁸See Spagnolo (2005) or Buccirosi and Spagnolo (2007) for a research agenda on corporate governance factors and collusion.

⁹Recent cases of cartels operating in relatively similar sectors in the EU (TV and computer monitor tubes) and in the US (LCD producers) clearly witness this. The decision of the EC involved fines of about € 1.4 billion on seven of the participating firms; the DOJ decision, on the other hand, fined for about \$ 1.39 billion eight firms and inflicted a jail sentence to two senior executives of the Taiwanese company AU Optronics. Besides reflecting different approaches to cartel punishment, these cases

Lambertini and Trombetta (2002) consider optimal delegation when managers can collude on the product market after owners have set their incentives schemes, either collusively or not. They show that if owners collude when managers behave non-cooperatively, then collusion becomes more difficult to sustain. However, if both managers and owners can collude, the outcome depends on the level of patience of both agents and owners can "exploit" managers' patience to improve on their outcomes. Our paper assumes that delegation to managers takes place and addresses the issue of the effect of different types of fines to deter collusion.

The rest of the paper is structured as follows. In Section 2 we present the basic model and the features of the two types of fines and provides some results. Section 3 focuses on the welfare effects of different approaches to cartel deterrence. Section 4 discusses the results and concludes. All proofs are in the Appendix.

2 Model and Analysis

We consider a duopoly model in which firms compete *à la Cournot* in the final product market. The inverse demand is linear, and given by $p = a - Q$, where $Q = q_1 + q_2$. The marginal cost is constant and equal to c for both firms. An important feature of our model is that firms are run by managers, who maximise a combination of firm's profit (π_i) and sales (q_i). This is captured by the following objective function (Vickers, 1985; Lambertini and Trombetta, 2002):

$$m_i = \pi_i + \theta_i q_i, \quad i = 1, 2, \quad (1)$$

where θ_i is the relevance of sales and represents a measure of delegation.¹⁰ We assume that the delegation parameter is given and, as firms are symmetric, then incentives schemes are such that $\theta_1 = \theta_2 = \theta$.

For simplicity of notation and without loss of generality, we set $A = a - c$. The managers' objective function can be rewritten as follows:

$$m_i = (A - Q + \theta)q_i, \quad i = 1, 2, \quad (2)$$

and A is high enough to guarantee that all quantities and profits are non-negative.

show how the corporate structure of the vast majority of the firms involved managers who have been delegated decisions by its owners or shareholders.

¹⁰When they maximise m_i , managers also maximise their compensation as their remuneration is proportional to m_i .

The basic stage game is repeated infinitely many times. In each stage, managers decide whether to play non-cooperatively, or to produce the collusive output. As a result, the payoffs for each manager are denoted respectively as m_i^N , m_i^C , and m_i^D , where N indicates the Cournot-Nash equilibrium, C the collusive equilibrium, and D the deviation from collusion, when the rival sticks to its cartel output level. To simplify notation, by using symmetry, we remove subscript i . In absence of fines, it is immediate to verify that $m^N = (A + \theta)^2/9$, $m^C = (A + \theta)^2/8$ and $m^D = 9(A + \theta)^2/64$.

Collusion is sustained through a grim trigger strategy (Friedman, 1971): if one firm deviates from the collusive agreement, it is punished by reverting to Cournot competition forever. Let $\alpha_i \in [0, 1]$ define manager i 's individual discount factor. We assume that players' intertemporal preferences are pairwise symmetric, hence $\alpha_1 = \alpha_2 = \alpha$.

Standard derivations show that managers form a sustainable cartel when their discount factor is sufficiently high, *i.e.* $\alpha \geq \frac{m^D - m^C}{m^D - m^N}$. In the present setting, this implies:

$$\alpha \geq \frac{9}{17} \equiv \alpha^* \tag{3}$$

which is the same threshold level than in the game without delegation.¹¹ This represents our benchmark case.

For future reference, the collusive per-firm outcome is $q^C = (A + \theta)/4$, and the Cournot-Nash one is $q^N = (A + \theta)/3$. Moreover, firms' symmetric net profits are respectively given by $\pi^C = [(A - \theta)(A + \theta)]/8$ and $\pi^N = [(A - 2\theta)(A + \theta)]/9$. We assume that $A \geq 2\theta$ to ensure the non-negativity of such profits.

3 The fight against cartels: two types of fines

In our model, the antitrust authority can use two types of fines to deter cartel formation. The first type targets the profits of the firm, while the second directly affects the manager's delegation contract. We suppose that a cartel agreement requires some communication between managers, therefore generating tangible evidence. However, consistently with the literature (Rey, 2003; Motta and Polo, 2003; Aubert et al., 2006; Avramovich, 2010), we assume that the evidence disappears at the end of each period and therefore firms are not sanctioned in case of deviation.

¹¹For more details, see Lambertini and Trombetta (2002), p. 362.

3.1 The profit based fine

The antitrust authority is supposed to detect the collusive behaviour between managers with probability ρ .¹² When this happens, it launches an investigation leading to a successful prosecution of the cartel. A total fine F is imposed implying that each firm pays $F/2$. Type I errors (firms which do not collude but are still prosecuted) are assumed not to occur, whereas Type II errors (colluding firms are not fined) do.

Under these assumptions, the colluding managers jointly maximise:

$$M = (A - Q + \theta)Q - \rho F. \quad (4)$$

Taking the first-order condition (FOC) and imposing symmetry, we find that each firm still produces $q^C = (A + \theta)/4$, as the expected fine ρF enters as a fixed cost. This implies that the strategic response by the cheating player also remains the same, and so does its final payoff, as we assumed that firms are not punished in case of deviation. Then, $m^D = 9(A + \theta)^2/64$. As Cournot-Nash profits do not depend on the fine, we obtain again $m^N = (A + \theta)^2/9$.

The only difference w.r.t. the benchmark case is represented by the expected payoff in case of collusion, which results in $m_P^C = (A + \theta)^2/8 - \rho F/2$, where subscript P indicates the change brought by the profit based fine.

As the incentive to form a cartel appears in presence of a prisoners' dilemma (*i.e.* individual collusive payoff must be higher than Cournot payoff), we assume that:

$$m_P^C \geq m^N \iff \rho F \leq \bar{T} = \frac{(A + \theta)^2}{36}, \quad (5)$$

with \bar{T} being the the maximum level of the profit based fine.¹³

Under condition (5), managers can sustain the collusive agreement over time if and only if their discount factor satisfies the following condition:

$$\alpha \geq \frac{9}{17} \left[1 + \frac{32\rho F}{(A + \theta)^2} \right] \equiv \alpha_P. \quad (6)$$

The above expression showcases the most important features of the profit based fine. Obviously, the higher the expected fine, the more difficult is to collude. Interestingly, for any given level of ρF , notice that α_P decreases in θ , as the manager's

¹²The exogeneity of the parameter ρ eliminates several potential effects of the antitrust policy. If ρ depended on the firms' prices (or quantities), then the cartel would adopt complex price patterns (Harrington, 2004 and 2005; Harrington and Chen, 2006).

¹³This, *a fortiori*, also guarantees that cartel payoffs are positive.

payoff positively depends on the delegation parameter. In other words, to achieve the same level of deterrence (α_P) the expected fine needs to be bigger, the more powers are delegated to the managers (θ).

Obviously, in absence of the antitrust policy ($\rho F = 0$), α_P would coincide with the benchmark the threshold value $\alpha^* = 9/17$. In the opposite scenario, $\alpha_P = 1$ when $\rho F = \bar{T}$, and the collusive agreement is not an option for managers.

3.2 The delegation based fine

If managers are delegated decisions on behalf of the owners, then the antitrust authority may decide to punish them in a more direct way than by sanctioning the firm. In other words, the authority may target the manager's delegation parameter θ . In our model, this implies that a fine f is levied on θ when collusion is detected, and this occurs with probability ρ . In this case, the colluding managers jointly maximise:

$$M = [A - Q + (\theta - \rho f)] Q, \quad (7)$$

where $\rho f \cdot Q$ indicates the total amount of the expected delegation based fine.¹⁴

Taking FOC and using symmetry, the individual collusive outcome is given by $q_D^C = (A + \theta - \rho f)/4$, where additional subscript D indicates that collusive output levels change when a delegation based fine is levied. Hence:

Remark 1 *Collusive output is affected by the delegation based fine. In particular, one can immediately notice that $q_D^C < q^C$.*

The expected fine is now taken into account by the colluding managers in their maximisation process, and it induces a reduction in the output level. This will have important consequences in terms of social welfare, as we will discuss in the next section. The corresponding payoff of a manager participating in the cartel can be easily obtained, and it amounts to $m_D^C = (A + \theta - \rho f)^2/8$.

Interestingly, following Remark 1, the strategic response of the deviating player now includes the expected fine. This in turn affects the deviation payoff, which amounts to $m_D^D = [3(A + \theta) + \rho f]^2/64$. As a consequence:

¹⁴The expected fine can be interpreted as a monetary reduction of the managers' payment or an expected utility loss deriving from the risk of being caught colluding. Although we underlined that our model does not explicitly model criminal sanctions, in a more general interpretation the delegation based fine can be thought as a reduced form that captures the expected loss of reputation, benefits and other damages incurred by a guilty manager.

Remark 2 *The delegation based fine increases the incentive to deviate from the collusive outcome, as $m_D^D > m^D$.*

A complete evaluation of the respective effectiveness of the two policy instruments will be performed in the next section. However, Remark 2 already unveils one of the point of strength of the delegation based fine *vis-à-vis* the profit based fine: deviating from a collusive agreement becomes more profitable for the manager.

As Cournot-Nash payoffs are not affected by the fine, we can now compute the threshold value of the discount factor which sustains collusion under the delegation based fine. We need to ensure that the individual collusive payoff is still higher than Cournot one. This requires:

$$m_D^C \geq m^N \iff \rho f \leq \bar{t} = \frac{(A + \theta)(3 - 2\sqrt{2})}{3}. \quad (8)$$

We assume that the condition expressed in (8) holds throughout the paper.

Under condition (8), managers have an incentive to form a cartel if and only if:

$$\alpha \geq \frac{9}{17} \left[1 + \frac{64 \rho f [5(A + \theta) - 2\rho f]}{(A + \theta + 3\rho f) [17(A + \theta) + 3\rho f]} \right] \equiv \alpha_D \quad (9)$$

Similarly to the previous case, the higher the expected fine, the more difficult is to collude. Moreover, for any given level of the expected fine, α_D also decreases in θ . Finally, it is immediate to verify that $\alpha_D \equiv \alpha^*$ when the expected fine tends towards zero, and that $\alpha_D = 1$ when $\rho f = \bar{t}$.

3.3 Profit based and delegation based fine: a comparison

The two types of fines can be compared and conditions can be found for which one is more effective than the other in deterring collusion. The following holds:

Proposition 1 *Suppose $\rho F \leq \bar{T}$ and $\rho f \leq \bar{t}$, then a profit based fine is more effective in deterring collusion if and only if:*

$$\rho F > \tilde{T} = \frac{2\rho f (A + \theta)^2 (5(A + \theta) - 2f\rho)}{(A + \theta + 3f\rho) (17(A + \theta) + 3\rho f)}.$$

The opposite holds, obviously, when $0 < \rho F < \tilde{T}(\rho f)$. Finally, the threshold value \tilde{T} increases with θ .

Proof See the Appendix.

Proposition 1 conveys two main messages. The first one has an intuitive appeal: the instrument that prevails in deterring cartels depends on the relative intensity of the profit based fine as compared to the delegation based fine. The second one is more interesting as it pertains to the delegation mechanism. The fact that \tilde{T} increases with θ implies that a profit based lump-sum fine is more likely to deter cartels if owners retain most of the decisional power. On the contrary, a distortive fine, targeting managers more directly, is more effective when managers are delegated a high decisional power.

Finally, notice that the comparison depends on the probability of collusion being detected despite this is identical in the two settings: this is due to the fact that the delegation based fine is distortive and affects the managers' choices.

Revenue equivalence

The results in Proposition 1 are strongly affected by the possibility that the antitrust authority charges two different levels of sanctionatory fines, depending on whether it opts for the profit based fine, or for the delegation based fine. However, it would be probably more relevant for the policy maker to find out which of the two instruments performs better for a given value of the expected revenue.¹⁵

In this context, a revenue equivalence requirement implies:

$$\rho F = \rho f \cdot 2q_D^C. \quad (10)$$

Following (10), condition (5) can be re-written as:

$$\rho f < \frac{(A + \theta)}{6} (3 - \sqrt{7}). \quad (11)$$

By comparing (11) with (8), we find that the binding condition is \bar{t} . This already seems to indicate a superior performance of the delegation based instrument, which is more efficient in eliminating the incentive to collude. Moreover, under (10) the threshold discount factor α_P that appears in (6) can be re-expressed as:

$$\alpha_P^{re} \equiv \frac{9}{17} \left[1 + \frac{16\rho f (A + \theta) - 16(\rho f)^2}{(A + \theta)^2} \right], \quad (12)$$

where superscript *re* indicates revenue equivalence. It follows that:

¹⁵This may especially be the case if the antitrust authority has limited resources, which are mainly generated by the fines imposed to and collected from detected cartels.

Proposition 2 *Under (10) and assuming $\rho f < \bar{t}$, we obtain that $\alpha_D > \alpha_P^{re}$: a delegation based fine is more effective than a profit based lump-sum fine in deterring cartel formation.*

Proof See the Appendix.

The main message of Proposition 2 is that the delegation based fine is more effective in deterring collusion than the profit based fine. We already know that, unlike the lump sum fine, the delegation based fine makes the deviation payoffs more appealing (Remark 2), thus reducing the incentive to stick to the collusive outcome. This occurs because the best response output of the deviating manager is increased as the opponent expects to be fined and, hence, reduces its output.

In addition, the delegation based instrument, being distortive (Remark 1), has a stronger impact on manager's collusive payoff than the profit based one. Indeed, under revenue equivalence, $(m_P^C)^{re} = \left[(A + \theta)^2 - 2\rho f(A + \theta - \rho f) \right] / 8$. It is immediate to demonstrate that the collusive payoff is lower under the delegation based fine, as $m_D^C - (m_P^C)^{re} = -(\rho f)^2 / 8$.

The overall outcome of these two forces is to increase the value of the minimum discount factor that sustains collusion under the delegation based fine as compared to the profit based one.

4 Welfare implications

The main message to be taken from the previous section is that the delegation based fine, although distortive, is more effective in deterring cartels in comparison to a profit based fine. Based on an *ex-ante* reasoning, it should therefore be implemented by the antitrust authority. However, if it misses the mark, a delegation based instrument may have an *ex-post* negative impact on consumer surplus, as the quantity produced under collusion would shrink. The aim of this section is to explore this possible trade-off. In doing so, we focus on the expected welfare generated by each instrument.

In our setting, cartel deterrence crucially depends on the patience of the managers. To keep our model as simple as possible, we assume that from the antitrust authority perspective there is a uniform distribution of the managers' discount factor, *i.e.* $\alpha \sim U[0, 1]$. This may be the case if the antitrust authority has no prior information about the managers that operate in the market: as a consequence, any discount factor is equally likely to be realised.

The expected welfare can then be written as:

$$EW = \alpha W^N + (1 - \alpha) W^C, \quad (13)$$

where W^N is a generic measure of welfare generated under Cournot-Nash competition, and W^C is the one associated to the cartel. This allows us to compare the impact of the two fines on both consumer surplus and total welfare in a relatively simple way.

4.1 Consumer surplus

The top priority of antitrust authorities in many countries is to protect consumers interests.¹⁶ Hence, it is worth evaluating the impact on consumer surplus of the two instruments that we consider. As the demand function is linear, and given that we consider a symmetric duopoly, consumer surplus can be written as:

$$CS = Q^2/2 \equiv 2q^2. \quad (14)$$

In the benchmark case, in which no penalty is implemented, collusion is sustainable for $\alpha > \alpha^* = 9/17$. Following (13), the expected consumer surplus is:

$$ECS^* = \alpha^* [2(q^N)^2] + (1 - \alpha^*) [2(q^C)^2] = \frac{3(A + \theta)^2}{17}. \quad (15)$$

When the non-distorting profit based fine is adopted, the expected consumer surplus amounts to:

$$ECS_P = \alpha_P [2(q^N)^2] + (1 - \alpha_P) [2(q^C)^2] = \frac{3(A + \theta)^2 + 28\rho F}{17}, \quad (16)$$

which is obviously higher than in the benchmark case. Relevant output levels q^N and q^C are unaffected by the fine, which yet increases the interval region where collusion is successfully deterred ($\alpha_P > \alpha^*$). This, in turn, reduces the probability that managers' factors discount support the collusive behaviour.

Turning to the delegation based fine, the expected consumer surplus is:

$$\begin{aligned} ECS_D &= \alpha_D [2(q^N)^2] + (1 - \alpha_D) [2(q_D^C)^2] = \\ &= \frac{3(A + \theta)^3 + 15(A + \theta)^2 \rho f - 13(A + \theta) (\rho f)^2 + 3(\rho f)^3}{17(A + \theta) + 3\rho f}. \end{aligned} \quad (17)$$

¹⁶The dispute on the appropriate standard for antitrust enforcement seems still unsettled: see, for example, Pittman (2007) for more details.

This is the first case where the aforementioned trade-off appears. When comparing ECS_D with ECS^* , we have that $q_D^C < q^C$, as already acknowledged in Remark 1. However, collusion is less likely to occur, as $\alpha_D > \alpha^*$. Relatively simple algebraic calculations reveal that the latter effect dominates the former one, and therefore $ECS_D > ECS^*$.¹⁷

It follows that both a profit based fine and a delegation based fine enhance the expected consumer surplus in comparison to the benchmark case, where no policy instrument was adopted. The introduction of either type of fine brings forth a deterrence effect that not only makes collusion more difficult to be sustained, but it also benefits consumers.

Under revenue equivalence, it is also possible to evaluate which one is better from a consumer's standpoint. We find that:

Proposition 3 *Under (10) and assuming $\rho f < \bar{t}$, we find that $ECS_D > ECS_P^{re}$: a delegation based fine is always preferred by consumers in comparison to a profit based fine.*

Proof see the Appendix.

The delegation based fine is not only more effective in deterring collusion, but it is also preferred by consumers. This holds despite of its distortive effect on collusive quantities. The following decomposition helps to explain why this occurs:

$$ECS_D - ECS_P^{re} = \underbrace{(\alpha_D - \alpha_P^{re})}_{>0} \underbrace{[2(q^N)^2 - 2(q^C)^2]}_{>0} - \underbrace{(1 - \alpha_D)}_{>0} \underbrace{[2(q^C)^2 - 2(q_D^C)^2]}_{>0}. \quad (18)$$

Deterrence effect Expected distortionary effect

The difference in the expected consumer surplus under the two policy regimes can be represented by two components induced by the delegation based fine in comparison to the profit based one: a "deterrence effect" and an "expected distortionary effect". The former captures the positive effect on consumer surplus that comes from the reduction in the interval region that sustains collusion, and the corresponding increase in the output level produced. The latter represents the reduction in consumers surplus that derives from the lower output level which we obtain in presence of a delegation based fine when collusion persists.

¹⁷More precisely, $ECS_D - ECS^* = \frac{\rho f [246(A+\theta)^2 - 221\rho f(A+\theta) + 51(\rho f)^2]}{289(A+\theta) + 51\rho f} > 0$ under the parametric restrictions imposed on ρf , A , and θ .

The result in Proposition 3 implies that the "deterrence effect" always dominates the "expected distortionary effect". Following the basic assumptions of our paper, a delegation based fine increases the interval region where managers compete non-cooperatively. In addition, although such a fine induces a loss in consumer surplus when collusion occurs, it also reduces the probability that this will happen, as a cartel is less likely to be formed.

Finally, comparative statics reveal that $\partial(ECSD - ECS_P^{re})/\partial\theta > 0$: when θ increases, the delegation based fine is even more beneficial to consumers. As the power delegated to the managers are extended, the benefits of deterring the cartel further increase. The enhanced deterrence effect, by increasing the probability to obtain an even richer Cournot-Nash outcome, dominates even more the distortion generated by the delegation based instrument.

4.2 Aggregate surplus

Assume that the antitrust authority does not limit its attention only to consumer's protection, but it considers instead total social welfare. Following Vickers (1985), the managers' compensations linearly depends on m . They do not affect total welfare, as they constitute a transfer between the firms and the managers. A similar observation applies to the revenue collected by the antitrust authority, which corresponds to the expected amount paid by collusive managers. Total welfare can therefore be written as:¹⁸

$$TW = 2\pi + 2q^2. \quad (19)$$

where π represents firms' profits as computed in Section 2.

Following the same reasoning as in (13), the expected welfare in the benchmark case amounts to:

$$ETW^* = \alpha^* [2\pi^N + 2(q^N)^2] + (1 - \alpha^*) [2\pi^C + 2(q^C)^2] = \frac{(7A - 3\theta)(A + \theta)}{17}. \quad (20)$$

¹⁸The complete expression for total welfare is: $TW = \sum_{i=1}^2 (OS_i) + \sum_{i=1}^2 (MS_i) + CS + AA$, where OS is the owner surplus, MS the manager surplus, CS the consumer surplus, and AA the revenue cashed by the antitrust authority. Following the previous discussion, it is immediate to prove that this boils down to $TW = 2\pi + 2q^2$. Notice that the latter expression applies to all regimes, including both a profit and delegation based fine, assuming that the firms' profits in presence of a cartel is gross of both the expected fine and the managers' payment, *i.e.* $\pi_i = (p - c)q_i$.

In the presence of a profit based fine, we find:

$$\begin{aligned} ETW_P &= \alpha_P [2\pi^N + 2(q^N)^2] + (1 - \alpha_P) [2\pi^C + 2(q^C)^2] = \\ &= \frac{(7A - 3\theta)(A + \theta)}{17} + \frac{4(5A - 7\theta)\rho F}{17(A + \theta)}. \end{aligned} \quad (21)$$

Notice that $ETW_P \geq ETW^*$ when (5) holds. The profit based fine raises the expected welfare. The result is very intuitive: the redistributive effect that takes place when using a lump-sum transfer does not change total welfare in the two scenarios. It does increase, however, the probability to achieve the welfare enhancing Cournot-Nash outcome, as the fine shifts the threshold discount factor from α^* to α_P .

Turning to the delegation based fine, the expected welfare is:

$$\begin{aligned} ETW_D &= \alpha_D [2\pi^N + 2(q^N)^2] + (1 - \alpha_D) [2\pi_D^C + 2(q_D^C)^2] = \\ &= \frac{(7A - 3\theta)(A + \theta)^2 + (11A - 15\theta)(A + \theta)\rho f + (A + 13\theta)(\rho f)^2 - 3(\rho f)^3}{17(A + \theta) + 3\rho f}. \end{aligned} \quad (22)$$

The differences with the previous case are evident: not only does the threshold discount factor increase from α^* to α_D , but also the collusive welfare component W^C is now affected by the output distortion implied by the delegation based fine.

The change in the threshold discount factor improves expected welfare, while the quantity distortion moves in the opposite direction. Algebraic calculations reveal that, under the conditions imposed in our model, the first effect always dominates the second one. The delegation based fine is therefore welfare enhancing in comparison to the benchmark case.

We can now proceed to compare the effects of the two types of fines under the assumption of revenue equivalence. The following result holds:

Proposition 4 *Under (10) and assuming $\rho f < \bar{t}$, the delegation based fine increases total welfare more than a profit based fine if and only if $\rho f > \tilde{t}$, with \tilde{t} increasing in θ . Conversely, if $0 < \rho f < \tilde{t}$, then a profit based fine is preferable.*

Proof see Appendix.

Differently from the expected consumer surplus, here there is no policy instrument that always prevails for the antitrust authority. The relative benefit of a delegation based fine in comparison to a profit based fine can be written as:

$$\begin{aligned}
ETW_D - ETW_P^{re} &= (\alpha_D - \alpha_P^{re}) \underbrace{\left\{ \underbrace{(2\pi^N - 2\pi^C)}_{<0} + \underbrace{[2(q^N)^2 - 2(q^C)^2]}_{>0} \right\}}_{\text{Deterrence effect}} \\
&\quad - \underbrace{(1 - \alpha_D) \left\{ \underbrace{(2\pi^C - 2\pi_D^C)}_{\geq 0} + \underbrace{[2(q^C)^2 - 2(q_D^C)^2]}_{>0} \right\}}_{\text{Expected distortionary effect}}. \quad (23)
\end{aligned}$$

By comparing (18) and (23) it is possible to understand the reason why the profit based fine can be preferred in terms of total welfare. The "deterrence effect", which remains positive, is unambiguously reduced by the component $2\pi^N - 2\pi^C$, which indicates the loss in the profit surplus when the cartel is successfully deterred. The "expected distortionary effect", on the contrary, does not provide a clear indication on how it changes. It remains negative, but given that $2\pi^C - 2\pi_D^C \geq 0$, its absolute value can either increase or decrease. Algebraic calculations, however, confirm that $|2\pi^N - 2\pi^C| > |2\pi^C - 2\pi_D^C|$. The reduction in the weight of the "deterrence effect" dominates the change in the "expected distortionary effect".

The result of Proposition 4 are summarized in Figure 1.¹⁹ The interval region in which $\tilde{t} < \rho f < \bar{t}$ represents all the combinations of expected fine ρf and delegation parameter θ for which the "deterrence effect" is still stronger than the "expected distortionary effect". The explanation is relatively simple. When the expected fine ρf is sufficiently high, the deterrence effect of a delegation based fine increases. This, in turn, reduces the relative weight of the "expected distortionary effect". Although *ex post* distortionary effects may increase, it is *ex ante* less likely that a cartel takes place. The delegation based fine is therefore preferred in terms of total welfare.

On the contrary, when $0 < \rho f < \tilde{t}$, the opposite holds. For low values of the expected fine, indeed, the distortionary effect is likely to increase, as both quantities and profits are negatively affected by the delegation based fine. This stronger distortionary effect may more than compensate a weakened deterrence effect, thereby increasing the chances that the profit based fine be preferable in terms of expected total welfare.

¹⁹Remember that the initial condition that we imposed was $A \geq 2\theta$, which verifies that equilibrium profits are non-negative in the basic model. Picture 1 has been depicted for $A = 5$.

Figure 1 Welfare effects

Lastly, notice that the area where $ETW_D > ETW_P^{re}$ is decreasing in θ . This appears counterintuitive, especially when compared with the consumer surplus case, where the "gain" brought by the delegation based fine was enhanced by θ . However, introducing profit surplus may alter the outcome. In fact, deterring a cartel implies a decrease in profits, and such a negative effect is amplified when more powers are delegated to managers. Using (23), one can find that $\partial |2\pi^N - 2\pi^C| / \partial \theta > \partial |2\pi^C - 2\pi_D^C| / \partial \theta$: a higher θ reduces more the "deterrence effect" than the "expected distortionary effect". More in general, the negative effect of θ on profit surplus dominates its positive effect on consumer surplus, thus explaining the result.

5 Concluding Remarks

The fight against collusive behaviour in the US and in the EU is based on similar principles. However, substantial differences still exist, especially regarding the instruments adopted to carry out cartel deterrence. In particular, the criminal punishment of managers is perceived as a crucial deterrent in the US but not in the EU.

This paper addresses the effectiveness of different types of instruments in deterring cartels. In particular, we focus on fines levied on profits and fines targeting the powers delegated to managers. The aim is to model in a stylised way the "punish-the-firm" versus "punish-the-person" controversy and analyse its economic consequences. As

the majority of firms involved in cartel cases are managerial firms, we analyse these two types of antitrust instruments in the context of the delegation model of Vickers (1985) and Fershtman and Judd (1987).

Our results indicate that the effectiveness of each type of instrument is closely related to the amount of powers delegated to the managers. Intuitively, a delegation based fine is more likely to effectively deter collusion when the decisional power delegated to managers is sufficiently high. If the comparison is performed under revenue equivalence, then the delegation based fine is more effective because its distortionary effect further reduces the incentives to collude in comparison to the profit based fine.

Such a distortion, however, may have a negative consequences on the overall surplus if managers are patient enough to sustain collusion, despite the antitrust efforts. In this case, we identify an important trade-off that has largely been overlooked in the existing literature between *ex-ante* effective deterrence and *ex post* output reduction if collusion takes place.

The trade-off does not arise if the antitrust authority focuses on consumer surplus as a measure of social welfare. In such a case, the delegation based fine is not only more effective in deterring cartels, but it also further expands expected welfare than the profit based fine. The same conclusion, however, does not apply if we consider total surplus. The delegation based fine erodes cartel profits more than the profit based fine, reducing the profit surplus. The interplay between the amount of the fine and the delegation parameter provides further insights on the relative weight of consumer surplus *vis à vis* profit effects and helps determining the overall desirability of each type of fine.

Although our results are obtained in a very stylised model, we believe that the main message of the paper can have relevant policy implications. Distortive fines maybe very tempting for antitrust authorities. They allow for more effective cartel deterrence, thereby benefiting consumers. However, if productive efficiency is also relevant, then less distortive instruments can achieve higher overall welfare by limiting the loss in profit surplus. This holds in particular for relatively low levels of the expected punishment.

Ultimately, according to the results of our welfare analysis, the choice of the best policy option may drive antitrust authorities back to the long and fierce debate about the correct welfare standard to be adopted in competition policy: consumer surplus or total welfare?

Our work can be extended in different directions. We assumed that owners delegated a fixed amount θ to the managers. This can be relaxed to fully characterize the strategic interaction between owners and managers (see Lambertini and Trombetta, 2002). In such a context, the effectiveness of each instrument would be affected by the decisions of the owners. It can be conjectured that the most effective instrument would therefore depend on the strategic decisions of the owners at the initial stage and there could be cases in which owners can exploit managers' patience in order to bypass the efforts of the antitrust authority. Finally, leniency programs can be incorporated in our framework to study how they would interact with different types of fines and how this may affect our current results.

Appendix

Proof of proposition 1

Assume that conditions (5) and (8) hold. We compare the two threshold discount factors to obtain:

$$\Delta\alpha = \alpha_P - \alpha_D = \frac{288}{17} \left\{ \frac{\rho F}{(A + \theta)^2} - \frac{2\rho f (5(A + \theta) - 2\rho f)}{[(A + \theta) + 3\rho f][17(A + \theta) + 3\rho f]} \right\}$$

Algebraic calculations reveal that:

$$\Delta\alpha > 0 \iff \rho F > \tilde{T} = \frac{2\rho f (A + \theta)^2 (5(A + \theta) - 2\rho f)}{(A + \theta + 3\rho f)(17(A + \theta) + 3\rho f)},$$

where we maintain that $\rho f < \bar{t}$. Moreover, $\tilde{T} < T$, as it can be easily ascertained. Under condition (8), it is immediate to verify that \tilde{T} is increasing in both the expected fine ρf and the delegation parameter θ :

$$\frac{\partial \tilde{T}}{\partial \rho f} = \frac{34(A + \theta)^3 (A + \theta + \rho f) [5(A + \theta) - 9\rho f]}{(A + \theta + 3\rho f)^2 [17(A + \theta) + 3\rho f]^2} > 0,$$

$$\frac{\partial \tilde{T}}{\partial \theta} = \frac{2(A + \theta)\rho f [85(A + \theta)^3 + 540(A + \theta)^2\rho f + 27(A + \theta)(\rho f)^2 - 36(\rho f)^3]}{(A + \theta + 3\rho f)^2 [17(A + \theta) + 3\rho f]^2} > 0.$$

This completes the proof. ■

Proof of proposition 2

Remember that the comparison between (??) and (9) takes place under the restriction $t < \bar{t} = [(A + \theta) (3 - 2\sqrt{2})] / 3$. We obtain:

$$\Delta\alpha^{re} = \alpha_P^{re} - \alpha_D = -\frac{432\rho f}{17} \frac{3(\rho f)^3 + 15(A + \theta)(\rho f)^2 - 15(A + \theta)^2\rho f + (A + \theta)^3}{(A + \theta)^2(A + \theta + 3\rho f)(17A + 17\theta + 3\rho f)}.$$

Under the restriction imposed, the sign depends only on the term:

$$3(\rho f)^3 + 15(A + \theta)(\rho f)^2 - 15(A + \theta)^2\rho f + (A + \theta)^3 \geq 0.$$

This term has three real and positive zeros that can not be identified but through trigonometric methods (*casus irreducibilis*). The relevant one is: $\widetilde{\rho f} = 0.79065(A + \theta) > \bar{t}$ implying that $\alpha_P^{re} - \alpha_D < 0$ for all values $0 < \rho f < \bar{t}$. ■

Proof of proposition 3

Consider revenue equivalence as expressed in (10). The expected producer surplus resulting from the profit based fine re-writes as follows:

$$ECS_P^{re} \equiv \frac{3(A + \theta)^2 + 28\rho f \cdot (A + \theta) - 28(\rho f)^2}{17}. \quad (24)$$

Assume that condition (11) holds. It is tedious but relatively simple to verify that

$$ECS_D - ECS_P^{re} = \frac{\rho f \left[8(A + \theta)^2 - 25(A + \theta)\rho f + 93(\rho f)^2 \right]}{289(A + \theta) + 51\rho f} > 0.$$

This completes the proof. ■

Proof of proposition 4

The comparison is performed for $0 < \rho f < \bar{t}$. The welfare differential can be written as:

$$ETW_D - ETW_P^{re} = \frac{f\rho \left(-3f^2\rho^2(7A + 31\theta) + f\rho(157A + 25\theta)(A + \theta) - 4(A + 2\theta)(A + \theta)^2 \right)}{17(A + \theta)(17(A + \theta) + 3f\rho)}.$$

The sign of this expression depends on the numerator. The expression as a function of ρf has one zero that is relevant in our domain, $\rho f = \tilde{t}(\theta)$ with

$$\tilde{t}(\theta) = \frac{(A + \theta) \left(157A + 25\theta - \sqrt{24313A^2 + 5690A\theta - 2351\theta^2} \right)}{6(7A + 31\theta)}.$$

The sign of $\partial\tilde{t}(\theta)/\partial\theta$ is the same than the sign of the following expression:

$$563597 A^3 + 44907 A^2 \theta - 55281 A \theta^2 + 72881 \theta^3 + \sqrt{24313 A^2 + 5690 A \theta - 2351 \theta^2} (-3593 A^2 + 350 A \theta + 775 \theta^2),$$

which can be shown to be positive under the assumption of our paper. It follows that $\tilde{t}(\theta)$ is increasing with θ . ■
